## Mastering Math: Your Comprehensive Guide to Solving Equations with Fractions

Fractions can sometimes feel like a riddle, a puzzle that trips up even the most enthusiastic math learners. But fear not! Solving math equations involving fractions is a skill that's not only achievable but also incredibly useful. From understanding recipes to calculating distances, fractions are everywhere. This guide will break down the process step-by-step, demystifying fractions and empowering you to tackle any equation with confidence. We'll cover everything from basic operations to more complex scenarios, ensuring you have a solid grasp of this fundamental math concept.

### Why Fractions? A Quick Refresher

Before we dive into solving equations, let's quickly remember what fractions are all about. A fraction represents a part of a whole. It's written as a numerator (the top number) over a denominator (the bottom number), like  $\frac{1}{2}$  or  $\frac{3}{4}$ . The denominator tells us how many equal parts the whole is divided into, and the numerator tells us how many of those parts we have. Understanding this basic concept is the foundation for working with them in equations.

### The Building Blocks: Basic Fraction Operations in Equations

Solving equations with fractions often hinges on mastering the four basic operations: addition, subtraction, multiplication, and division. Let's see how these play out when fractions are involved in an equation.

#### 1. Adding and Subtracting Fractions in Equations

When you encounter an equation requiring you to add or subtract fractions, the key is to have a **common denominator**. This means both fractions need to be divided into the same number of equal parts. **Finding a Common Denominator:** If the denominators are different, you'll need to find the **least common multiple (LCM)** of the denominators. For example, if you have  $\frac{1}{3} + \frac{1}{4}$ , the LCM of 3 and 4 is 12. **Equivalent Fractions:** Once you have the LCM, convert each fraction into an **equivalent fraction** with the common denominator. To do this, multiply both the numerator and the denominator of each fraction by the same number. In our  $\frac{1}{3} + \frac{1}{4}$  example:  $\frac{1}{3}$  becomes  $\frac{1 \times 4}{3 \times 4} = \frac{4}{12}$  and  $\frac{1}{4}$  becomes  $\frac{1 \times 3}{4 \times 3} = \frac{3}{12}$ . **Adding/Subtracting Numerators:** Now that the denominators are the same, you can simply add or subtract the numerators and keep the common denominator. So,  $\frac{4}{12} + \frac{3}{12} = \frac{7}{12}$ . **Example in an Equation:** Let's say you have the equation:  $x + \frac{1}{5} = \frac{3}{10}$ . To solve for  $x$ , you'd subtract  $\frac{1}{5}$  from both sides. First, find a common denominator for 5 and 10, which is 10.  $\frac{1}{5}$  is equivalent to  $\frac{2}{10}$ . So,  $x = \frac{3}{10} - \frac{2}{10}$ .  $x = \frac{1}{10}$ .

## 2. Multiplying Fractions in Equations

Multiplying fractions is refreshingly straightforward! You simply multiply the numerators together and the denominators together. **Numerator x Numerator:** Multiply the top numbers. **Denominator x Denominator:** Multiply the bottom numbers. **Example in an Equation:** Consider the equation:  $(\frac{2}{3}) * x = \frac{4}{9}$ . To isolate x, you need to get rid of the  $\frac{2}{3}$ . You can do this by multiplying both sides of the equation by the reciprocal of  $\frac{2}{3}$ , which is  $\frac{3}{2}$ .  $x = (\frac{4}{9}) * (\frac{3}{2})$   $x = \frac{(4 * 3)}{(9 * 2)}$   $x = \frac{12}{18}$  Now, simplify the fraction by finding the greatest common divisor (GCD) of 12 and 18, which is 6.  $x = \frac{12 \div 6}{18 \div 6}$   $x = \frac{2}{3}$ .

## 3. Dividing Fractions in Equations

Dividing fractions involves a clever trick: **"Keep, Change, Flip."** **Keep:** Keep the first fraction as it is. **Change:** Change the division sign to a multiplication sign. **Flip:** Flip the second fraction (find its reciprocal). Once you've done this, you're back to multiplying fractions, which we just learned! **Example in an Equation:** Let's solve:  $x / (\frac{1}{4}) = \frac{5}{8}$ . To isolate x, we multiply both sides by  $\frac{1}{4}$ .  $x = (\frac{5}{8}) * (\frac{1}{4})$   $x = \frac{(5 * 1)}{(8 * 4)}$   $x = \frac{5}{32}$ . Alternatively, consider an equation where you need to divide by a fraction:  $(\frac{3}{5})x = \frac{6}{7}$ . To solve for x, you need to divide both sides by  $\frac{3}{5}$ . This means multiplying by the reciprocal,  $\frac{5}{3}$ .  $x = (\frac{6}{7}) / (\frac{3}{5})$   $x = (\frac{6}{7}) * (\frac{5}{3})$   $x = \frac{(6 * 5)}{(7 * 3)}$   $x = \frac{30}{21}$  Simplify by dividing both numerator and denominator by their GCD, which is 3.  $x = \frac{10}{7}$ .

## Dealing with Mixed Numbers in Equations

Mixed numbers (like  $2 \frac{1}{3}$ ) can also appear in equations. Before you can perform operations, it's best to convert them into **improper fractions** (where the numerator is larger than the denominator). **Converting Mixed Numbers to Improper Fractions:** Multiply the whole number by the denominator, then add the numerator. Keep the same denominator. For  $2 \frac{1}{3}$ :  $(2 * 3) + 1 = 7$ . So,  $2 \frac{1}{3}$  becomes  $\frac{7}{3}$ . **Example in an Equation:** Solve:  $1 \frac{1}{2} + x = 3 \frac{1}{4}$ . First, convert the mixed numbers to improper fractions:  $1 \frac{1}{2} = \frac{3}{2}$   $3 \frac{1}{4} = \frac{13}{4}$  The equation becomes:  $\frac{3}{2} + x = \frac{13}{4}$ . To solve for x, subtract  $\frac{3}{2}$  from both sides. You'll need a common denominator for 2 and 4, which is 4.  $\frac{3}{2} = \frac{6}{4}$ . So,  $x = \frac{13}{4} - \frac{6}{4}$ .  $x = \frac{7}{4}$ . You can leave this as an improper fraction or convert it back to a mixed number:  $1 \frac{3}{4}$ .

## Equations with Variables on Both Sides (Involving Fractions)

Sometimes, your equation might have terms with fractions and variables on both sides. The strategy here is to gather all the variable terms on one side and all the constant terms (numbers without variables) on the other. **Example:** Solve:  $\frac{1}{2}x + \frac{1}{4} = \frac{3}{4}x - \frac{1}{8}$ . 1. **Move Variable Terms:** Let's move the x terms to the right side by subtracting  $\frac{1}{2}x$  from both sides. You'll need a common denominator for  $\frac{1}{2}$  and  $\frac{3}{4}$ , which is 4.  $\frac{1}{2}x$  is the same as  $\frac{2}{4}x$ .  $\frac{1}{4} = (\frac{3}{4})x - (\frac{2}{4})x - \frac{1}{8}$   $\frac{1}{4} = \frac{1}{4}x - \frac{1}{8}$  2. **Move Constant Terms:** Now, move the constant term ( $-\frac{1}{8}$ ) to the left side by adding  $\frac{1}{8}$  to both sides. You'll need a common denominator for  $\frac{1}{4}$  and  $\frac{1}{8}$ , which is 8.  $\frac{1}{4}$  is the same as  $\frac{2}{8}$ .  $\frac{2}{8} + \frac{1}{8} = \frac{1}{4}x - \frac{3}{8}$   $\frac{3}{8} = \frac{1}{4}x - \frac{3}{8}$  3. **Isolate the Variable:** To get x by itself, multiply both sides by the reciprocal of  $\frac{1}{4}$ , which is 4.  $x = (\frac{3}{8}) * 4$   $x = \frac{12}{8}$  Simplify the fraction by dividing by their GCD, 4.  $x = \frac{3}{2}$ .

## Clearing Denominators: A Powerful Shortcut

When equations become cluttered with fractions, there's a handy technique called "clearing the denominators." This involves multiplying the entire equation by the **least common multiple (LCM)** of all the denominators. This transforms the equation into one without fractions, making it much easier to solve. **Example:** Solve:  $\frac{1}{3}x + \frac{1}{2} = \frac{5}{6}$ . 1. **Find the LCM:** The denominators are 3, 2, and 6. The LCM of these numbers is 6. 2. **Multiply Each Term by the LCM:**  $6 * (\frac{1}{3}x) = 2x$   $6 * (\frac{1}{2}) = 3$   $6 * (\frac{5}{6}) = 5$  3. **The New Equation:** The equation now becomes:  $2x + 3 = 5$ . 4. **Solve the Simplified Equation:** Subtract 3 from both sides:  $2x = 2$ . Divide by 2:  $x = 1$ . This method is particularly useful for more complex equations with multiple fractional terms. It's a great way to simplify the problem and avoid errors with common denominators.

## Working with Variables in the Denominator

Equations with variables in the denominator require a bit more care. You'll often need to use the concept of **cross-multiplication** or multiply by the LCM of the denominators, similar to clearing denominators. **Example:** Solve:  $\frac{2}{x} = \frac{4}{6}$ .

1. **Cross-Multiplication:** Multiply the numerator of the first fraction by the denominator of the second, and set it equal to the numerator of the second fraction multiplied by the denominator of the first.  $2 * 6 = 4 * x$   $12 = 4x$  2. **Solve for x:**  $x = 12 / 4$   $x = 3$ . **Important Note:** When variables are in the denominator, you must always consider any values that would make the denominator zero. In this case,  $x$  cannot be 0, as division by zero is undefined.

## Tips for Success When Solving Fraction Equations

**Simplify When Possible:** Always look for opportunities to simplify fractions before or after performing operations. This reduces the chance of errors and makes the numbers more manageable. **Show Your Work:** Writing down each step clearly is crucial, especially when dealing with fractions. This helps you track your progress and makes it easier to spot mistakes. **Check Your Answer:** After solving an equation, substitute your answer back into the original equation. If both sides are equal, your solution is correct. This is a vital step in ensuring accuracy. **Practice Makes Perfect:** The more you practice solving fraction equations, the more comfortable and confident you'll become. Work through various examples, from simple to complex. **Understand the "Why":** Don't just memorize rules. Try to understand *why* you need a common denominator for addition/subtraction or why you flip a fraction for division. This deeper understanding will make you a more capable problem-solver.

## Conclusion: Embrace the Fraction Challenge!

With consistent practice and a clear understanding of the principles, you'll find that fractions are not a hurdle but a stepping stone to mathematical mastery. So go forth and solve those fraction equations with confidence!

Solving math equations with fractions is a foundational skill in mathematics that opens the door to more advanced problem-solving across science, finance, and everyday life. At its core, working with fractions involves understanding how to manipulate, compare, combine, and simplify expressions that include these part-based numbers. Mastering this skill not only strengthens numerical fluency but also builds confidence in handling complex quantitative challenges.

**Understanding Fractions and Their Role in Equations** Fractions represent parts of a whole, expressed as a numerator divided by a denominator. When embedded in equations, they require careful attention to algebraic rules and order of operations. Unlike whole numbers, fractions demand precise handling during addition, subtraction, multiplication, and division—especially when balancing both sides of an equation. Recognizing equivalent fractions, simplifying expressions, and converting between mixed numbers and improper forms are essential steps that ensure accuracy and clarity in solving. This understanding transforms abstract symbols into

meaningful solutions, forming the backbone of algebraic reasoning.

To solve equations involving fractions effectively, one must first isolate the fractional expression, often by eliminating denominators through multiplication by a common multiple. This step clears the equation of fractions, simplifying the process of solving for the unknown variable. For instance, in the equation  $\frac{2}{3}x = 8$ , multiplying both sides by 3 immediately removes the denominator, revealing  $x = 12$ . This technique not only streamlines calculations but also reduces the risk of errors commonly introduced during fractional arithmetic.

**Strategic Approaches to Solving Fraction Equations** A systematic approach is key when tackling fraction-based equations. Begin by identifying all terms containing the variable and those with constants. Next, determine the least common denominator (LCD) to unify the fractions. Clearing denominators preserves the equation's integrity while exposing a simpler linear form. Once denominators are eliminated, combine like terms and apply inverse operations to isolate the variable. This step-by-step method ensures logical progression and minimizes confusion. For equations involving multiple fractions, grouping terms or using substitution can further clarify relationships and simplify solutions.

Real-world applications of solving fraction equations abound—from calculating rates in compound tasks to adjusting recipes or managing budgets. For example, determining how long it takes two workers to complete a job together often involves adding fractions of work rates. Similarly, budgeting expenses across monthly periods requires accurate fraction manipulation to allocate resources fairly. These practical uses reinforce the relevance of the skill, demonstrating how mathematical reasoning directly supports decision-making and problem-solving in daily life.

**Benefits of Mastering Fraction Equation Solving** Proficiency in solving

## **Understanding the Basics: What Are Fractions and Why Do They Appear in Equations?**

Before diving into solving equations, let's revisit the fundamentals. A fraction represents a part of a whole. It's written as a ratio of two numbers: the numerator (the top number, representing the number of parts) and the denominator (the bottom number, representing the total number of equal parts the whole is divided into).

Fractions appear in equations for numerous reasons:

- 1. Representing Proportions:** Many real-world scenarios involve proportions, such as ratios of ingredients in a recipe or percentages.
- 2. Expressing Division:** A fraction bar is simply a division symbol. So,  $a/b$  is the same as  $a \div b$ .
- 3. Introducing Variables:** In algebra, fractions are often used when coefficients or constants involve parts of whole numbers.
- 4. Solving for Unknowns:** When solving for a variable that's multiplied or divided by a fraction, you'll naturally encounter fractional coefficients.

Key terms you'll encounter when working with fractions include:

- 1. Numerator:** The top number in a fraction.
- 2. Denominator:** The bottom number in a fraction.
- 3. Proper Fraction:** A fraction where the numerator is smaller than the denominator (e.g.,  $1/2$ ,  $3/4$ ).
- 4. Improper Fraction:** A fraction where the numerator is greater than or

equal to the denominator (e.g.,  $5/3$ ,  $7/7$ ).

5. **Mixed Number:** A whole number and a proper fraction combined (e.g.,  $2 \frac{1}{3}$ ).
6. **Equivalent Fractions:** Fractions that represent the same value, even though they have different numerators and denominators (e.g.,  $1/2 = 2/4 = 3/6$ ).
7. **Least Common Denominator (LCD):** The smallest common multiple of the denominators of two or more fractions. This is crucial for adding and subtracting fractions.
8. **Reciprocal:** The reciprocal of a number is 1 divided by that number. For a fraction  $a/b$ , its reciprocal is  $b/a$ . Multiplying a number by its reciprocal always results in 1.

## **The Golden Rule: Maintain Balance**

The most important principle in solving any equation, including those with fractions, is to maintain balance. Whatever operation you perform on one side of the equation, you must perform the exact same operation on the other side. This ensures that the equality remains true.

Think of an equation like a balanced scale. If you add weight to one side, you must add the same weight to the other to keep it level. This principle is the foundation for isolating the variable and finding its value.

## **Solving Simple Linear Equations with One Fraction**

Let's start with the most straightforward cases, where the equation contains only one fraction and a single variable. The goal here is to isolate the variable.

### **Case 1: Variable is in the Numerator**

Consider an equation like:  $x/3 = 5$

Here, 'x' is being divided by 3. To isolate 'x', we need to perform the

**inverse operation of division, which is multiplication. We'll multiply both sides of the equation by the denominator:**

$$(x/3) * 3 = 5 * 3$$

$$x = 15$$

**Verification: Substitute 15 back into the original equation:  $15/3 = 5$ . This is true, so our solution is correct.**

### **Case 2: Variable is Being Divided by a Fraction**

**Consider an equation like:  $x / (1/2) = 10$**

**Dividing by a fraction is the same as multiplying by its reciprocal. So,  $x / (1/2)$  is the same as  $x * 2$ .**

$$2x = 10$$

**Now, we isolate 'x' by dividing both sides by 2:**

$$2x / 2 = 10 / 2$$

$$x = 5$$

**Verification:  $5 / (1/2) = 5 * 2 = 10$ . Correct.**

### **Case 3: Variable is Multiplied by a Fraction**

**Consider an equation like:  $(2/3)x = 8$**

**To isolate 'x', we need to get rid of the fractional coefficient. We can do this by multiplying both sides by the reciprocal of the fraction ( $3/2$ ):**

$$(3/2) * (2/3)x = 8 * (3/2)$$

$$1x = 24/2$$

$$x = 12$$

**Verification:  $(2/3) * 12 = 24/3 = 8$ . Correct.**

### **Case 4: Variable is in the Denominator**

**Consider an equation like:  $6 / x = 3$**

**This is slightly trickier. First, we want to get 'x' out of the denominator. We can do this by multiplying both sides by 'x':**

$$(6/x) * x = 3 * x$$

$$6 = 3x$$

**Now, we isolate 'x' by dividing both sides by 3:**

$$6 / 3 = 3x / 3$$

$$2 = x$$

$$x = 2$$

**Verification:  $6 / 2 = 3$ . Correct.**

## **Solving Equations with Multiple Fractions**

**When equations involve more than one fraction, the strategy often involves simplifying the equation first, typically by eliminating the fractions entirely. The most effective way to do this is by using the Least Common Denominator (LCD).**

### **The Power of the LCD**

**The LCD is the smallest number that is a multiple of all the denominators in your equation. By multiplying every term in the equation by the LCD, you transform fractional terms into whole number terms, making the equation much easier to solve.**

### **Step-by-Step Example:**

**Let's solve the equation:  $x/2 + x/3 = 5$**

- 1. Identify the Denominators: The denominators are 2 and 3.**
- 2. Find the LCD: The smallest number that is a multiple of both 2 and 3 is 6.**
- 3. Multiply Every Term by the LCD: Multiply each term in the equation by 6:**

$$6 * (x/2) + 6 * (x/3) = 6 * 5$$

**4. Simplify: Cancel out common factors:**

$$(6/2)*x + (6/3)*x = 30$$

$$3x + 2x = 30$$

**5. Combine Like Terms: Add the 'x' terms:**

$$5x = 30$$

**6. Isolate the Variable: Divide both sides by 5:**

$$5x / 5 = 30 / 5$$

$$x = 6$$

**Verification: Substitute 6 back into the original equation:  $6/2 + 6/3 = 3 + 2 = 5$ . The equation holds true.**

### **Dealing with Mixed Numbers**

**If your equation contains mixed numbers, the first step is usually to convert them into improper fractions. This makes them easier to manipulate within the equation.**

**Example:**

**Solve:  $2 \frac{1}{4} + x = 5 \frac{1}{2}$**

**1. Convert Mixed Numbers to Improper Fractions:**

**1.  $2 \frac{1}{4} = (2*4 + 1)/4 = 9/4$**

**2.  $5 \frac{1}{2} = (5*2 + 1)/2 = 11/2$**

**2. Rewrite the Equation:**

$$9/4 + x = 11/2$$

**3. Isolate the Variable: Subtract  $9/4$  from both sides:**

$$x = 11/2 - 9/4$$

**4. Find a Common Denominator: The LCD of 2 and 4 is 4. Convert  $11/2$**

to an equivalent fraction with a denominator of 4:  $11/2 = 22/4$ .

**5. Perform Subtraction:**

$$x = 22/4 - 9/4$$

$$x = 13/4$$

**6. (Optional) Convert Back to a Mixed Number:  $13/4 = 3 \frac{1}{4}$ .**

**Verification:  $2 \frac{1}{4} + 3 \frac{1}{4} = 9/4 + 13/4 = 22/4 = 11/2 = 5 \frac{1}{2}$ . Correct.**

## **Advanced Techniques and Considerations**

As equations become more complex, several other strategies and considerations come into play.

### **Equations with Variables on Both Sides**

When variables appear on both sides of the equation, the goal is to gather all terms with the variable on one side and all constant terms on the other.

**Example:**

**Solve:  $(1/3)x + 2 = (1/2)x - 1$**

**1. Find the LCD: The denominators are 3 and 2. The LCD is 6.**

**2. Multiply by LCD:**

$$6 * ((1/3)x + 2) = 6 * ((1/2)x - 1)$$

$$6*(1/3)x + 6*2 = 6*(1/2)x - 6*1$$

$$2x + 12 = 3x - 6$$

**3. Gather Variable Terms: Subtract  $2x$  from both sides:**

$$12 = 3x - 2x - 6$$

$$12 = x - 6$$

**4. Gather Constant Terms: Add 6 to both sides:**

$$12 + 6 = x$$

$$18 = x$$

$$x = 18$$

**Verification:**  $(1/3)*18 + 2 = 6 + 2 = 8$ . And  $(1/2)*18 - 1 = 9 - 1 = 8$ .  
**Correct.**

## **Clearing Denominators in Inequalities**

The principles for solving inequalities with fractions are very similar to those for equations. You'll use the LCD to clear denominators.

However, remember the crucial rule for inequalities: if you multiply or divide both sides by a negative number, you must reverse the inequality sign.

**Example:**

**Solve:**  $x/4 - 1/2 < 1/4$

**1. Find LCD:** The denominators are 4 and 2. The LCD is 4.

**2. Multiply by LCD:**

$$4 * (x/4 - 1/2) < 4 * (1/4)$$

$$4*(x/4) - 4*(1/2) < 4*(1/4)$$

$$x - 2 < 1$$

**3. Isolate Variable:** Add 2 to both sides:

$$x < 1 + 2$$

$$x < 3$$

## **Common Pitfalls to Avoid**

**1. Forgetting to Multiply Every Term:** When using the LCD, ensure you multiply *\*every single term\** in the equation, not just the fractional ones.

**2. Errors in Sign:** Pay close attention to negative signs when combining

terms or moving them across the equals sign.

3. **Incorrectly Finding the LCD:** Double-check your LCD calculation, especially with larger denominators.

|----|----------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1  | What's the easiest way to add or subtract fractions with different denominators? | To add or subtract fractions with different denominators, find a common denominator. This is usually the least common multiple (LCM) of the denominators. Then, rewrite each fraction with the common denominator by multiplying the numerator and denominator by the same factor. Finally, add or subtract the numerators, keeping the common denominator the same. |
| 2  | How do I multiply fractions together?                                            | Multiplying fractions is straightforward! Simply multiply the numerators of the fractions together to get the new numerator, and multiply the denominators together to get the new denominator. You can simplify before or after multiplying, which often makes the numbers easier to work with.                                                                     |
| 3  | What's the trick to dividing fractions?                                          | Dividing fractions involves a neat trick: 'Keep, Change, Flip'. Keep the first fraction the same, change the division sign to multiplication, and flip the second fraction (its reciprocal). Then, multiply the fractions as you normally would.                                                                                                                     |
| 4  | How do I solve equations that have fractions in them?                            | To solve equations with fractions, the most common strategy is to eliminate the fractions by multiplying the entire equation by the least common multiple (LCM) of all the denominators. This transforms the equation into one with only integers, which you can then solve using standard algebraic techniques.                                                     |
| 5  | Can you give me a quick reminder on simplifying fractions?                       | To simplify a fraction, you need to find the greatest common divisor (GCD) of the numerator and the denominator. Then, divide both the numerator and the denominator by their GCD. The resulting fraction will be in its simplest form.                                                                                                                              |
| 6  | What's the difference between a proper, improper, and mixed number fraction?     | A <b>proper fraction</b> has a numerator smaller than its denominator (e.g., $\frac{3}{4}$ ). An <b>improper fraction</b> has a numerator greater than or equal to its denominator (e.g., $\frac{7}{3}$ ). A <b>mixed number</b> is a whole number combined with a proper fraction (e.g., $2 \frac{1}{3}$ ).                                                         |

|   |                                                                                      |                                                                                                                                                                                                                                                                                                                                   |
|---|--------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7 | How do I convert a mixed number into an improper fraction?                           | To convert a mixed number (like $3\frac{1}{2}$ ) into an improper fraction, multiply the whole number by the denominator ( $3 * 2 = 6$ ), and then add the numerator ( $6 + 1 = 7$ ). The result becomes the new numerator, and the denominator stays the same ( $7/2$ ).                                                         |
| 8 | How do I convert an improper fraction back into a mixed number?                      | To convert an improper fraction (like $11/3$ ) into a mixed number, divide the numerator by the denominator. The quotient is the whole number part of the mixed number. The remainder becomes the new numerator, and the denominator remains the same. So, 11 divided by 3 is 3 with a remainder of 2, making it $3\frac{2}{3}$ . |
| 9 | What if an equation has variables on both sides and fractions? How do I tackle that? | Start by eliminating all fractions by multiplying the entire equation by the LCM of the denominators. Once you have an equation with only integers, gather all terms with the variable on one side and constant terms on the other using addition and subtraction. Then, isolate the variable by dividing.                        |
