The solution manual for de Nevers' text typically addresses a wide array of problem types, each designed to test a specific aspect of air pollution control engineering. These can be broadly categorized as follows:

### **I. Source Emission Calculations and Characterization**

Many problems revolve around quantifying the amount of pollutants emitted from various industrial sources. This often involves understanding emission factors, process rates, and material balances. For instance, a typical question might require calculating the mass emission rate of sulfur dioxide ( $\text{SO}_2$ ) from a coal-fired power plant given the coal's sulfur content, firing rate, and the efficiency of a specific control device.

#### **Analytical Approach:**

Solving these problems necessitates a thorough understanding of units and conversions, as well as the ability to apply fundamental stoichiometric principles. Students must identify all relevant input and output streams, recognize the chemical reactions involved, and account for any inefficiencies or losses.

The solution manual will often demonstrate how to use emission factors provided in appendices or industry standards, emphasizing the importance of reliable data in [environmental impact assessment](#).

## **II. Atmospheric Dispersion Modeling**

Once emissions are quantified, understanding how these pollutants spread and dilute in the atmosphere is crucial for assessing ground-level concentrations. Questions in this area typically involve the application of dispersion models, such as the Gaussian plume model. These problems might ask to predict the maximum ground-level concentration of a pollutant downwind from a stack under specific meteorological conditions (wind speed, atmospheric stability) and source parameters (stack height, exit velocity, temperature).

### **Analytical Approach:**

This category demands a strong grasp of atmospheric science principles, including concepts like eddy diffusion, atmospheric stability classes, and plume rise. The solution manual will meticulously walk through the application of dispersion equations, explaining the significance of each variable and how meteorological data is incorporated. Understanding the limitations of these models, such as their applicability to steady-state conditions and flat terrain, is also an important analytical takeaway emphasized in the solutions.

### III. Control Device Performance and Design

A significant portion of air pollution control engineering focuses on the technologies used to remove pollutants from exhaust streams. Solution manual questions often explore the performance and design of these devices, including electrostatic precipitators (ESPs), baghouses (fabric filters), scrubbers (wet and dry), and catalytic converters.
