Differential Calculus Problems and Solutions: Master the Fundamentals with Practical Examples and Expert Guidance

Differential calculus, a cornerstone of mathematics, unlocks the secrets of change. This guide tackles common differential calculus problems and provides clear, step-by-step solutions, building a strong foundation for more advanced concepts. We'll explore applications and delve into practical examples to enhance your understanding. Differential calculus focuses on the *rate of change* of functions. Instead of simply looking at the value of a function at a specific point, differential calculus allows us to investigate how quickly that value is changing at that point. This "rate of change" is represented by the *derivative* of the function. Understanding derivatives is crucial for solving a wide range of problems in various fields, from physics and engineering to economics and finance. *Understanding the Derivative* The derivative of a function, often denoted as  $f'(x)$  or  $dy/dx$ , represents the instantaneous rate of change of the function at a specific point. Geometrically, it represents the slope of the tangent line to the curve of the function at that point. Finding the derivative involves applying specific rules and techniques based on the form of the function.

**Common Differential Calculus Problems and Their Solutions** Let's explore some common types of problems encountered in differential calculus and illustrate their solutions with examples: **1. Finding the Derivative of Polynomial Functions:** Polynomial functions are functions of the form  $f(x) = a_n x^n + a_{n-1} x^{n-1} + \dots + a_1 x + a_0$ , where 'a' represents constants and 'n' is a non-negative integer. To find the derivative, we use the power rule: • **Power Rule:**  $d/dx (x^n) = nx^{n-1}$  **Example:** Find the derivative of  $f(x) = 3x^2 + 2x - 5$ .

**Solution:**  $f'(x) = d/dx (3x^2) + d/dx (2x) - d/dx (5) = 6x + 2$  **2. Finding the Derivative of Trigonometric Functions:**

Trigonometric functions like  $\sin(x)$ ,  $\cos(x)$ , and  $\tan(x)$  have specific derivative rules: • **Derivative of  $\sin(x)$ :**  $d/dx (\sin(x)) = \cos(x)$  • **Derivative of  $\cos(x)$ :**  $d/dx (\cos(x)) = -\sin(x)$  • **Derivative of  $\tan(x)$ :**  $d/dx (\tan(x)) = \sec^2(x)$  **Example:** Find the derivative of  $f(x) = \sin(x) + 2\cos(x)$ . **Solution:**  $f'(x) = \cos(x) - 2\sin(x)$

**3. Applying the Chain Rule:** The chain rule is used to find the derivative of composite functions (functions within functions). • **Chain Rule:**  $d/dx [f(g(x))] = f'(g(x)) \cdot g'(x)$

**Example:** Find the derivative of  $f(x) = (x^2 + 1)^3$ . **Solution:** Let  $g(x) = x^2 + 1$  and  $f(u) = u^3$ . Then  $f'(u) = 3u^2$  and  $g'(x) = 2x$ .

Applying the chain rule:  $f'(x) = 3(x^2 + 1)^2 \cdot 2x = 6x(x^2 + 1)^2$  **4. Finding Tangent and Normal Lines:** The derivative helps determine the slope of the tangent line at a point on a curve. The normal line is perpendicular to the tangent line. **Example:**

Find the equation of the tangent line to  $f(x) = x^3$  at  $x = 2$ . **Solution:**  $f'(x) = 3x^2$ . At  $x = 2$ , the slope is  $f'(2) = 12$ . The point on the curve is  $(2, 8)$ . Using the point-slope form, the equation of the tangent line is  $y - 8 = 12(x - 2)$ .

**5. Optimization Problems:** Differential calculus is critical for solving optimization problems—finding maximum or minimum values of a function. This often involves finding critical points (where the derivative is zero or undefined). **Example:** A farmer wants to maximize the area of a rectangular enclosure using 100 meters of fencing. **Solution:** Let  $x$  and  $y$  be the sides of the rectangle. The perimeter is  $2x + 2y = 100$ , and the area is  $A = xy$ . Solve for  $y$  ( $y = 50 - x$ ) and substitute into the area equation:  $A(x) = x(50 - x) = 50x - x^2$ . Find the critical point by taking the derivative:  $A'(x) = 50 - 2x = 0$ . Solving for  $x$  gives  $x = 25$ . Therefore, the maximum area occurs when  $x = 25$  and  $y = 25$  (a square).

**Advantages of Mastering Differential Calculus:** • **Problem-solving skills:** Develops critical thinking and analytical abilities. • **Understanding change:** Provides a framework to understand and model dynamic systems. • **Applications in other fields:** Essential for physics, engineering, economics, and more. • **Foundation for advanced studies:** A prerequisite for integral calculus, multivariable calculus, and differential equations.

Think of differential calculus as your guide, helping you understand how things change and what their maximum or minimum values might be. It's the engine behind so much of modern science, engineering, economics, and even the algorithms that power your favorite apps.

In this comprehensive guide, we're going to dive deep into the world of differential calculus, focusing on the types of problems you're likely to encounter and, most importantly, how to conquer them with clear, step-by-step solutions. We'll break down complex concepts into digestible chunks, sprinkling in practical examples and insights to make your learning journey smoother and more engaging. So, grab your favorite beverage, settle in, and let's demystify differential calculus, one problem at a time!

## What Exactly is Differential Calculus?

At its core, differential calculus is about understanding instantaneous rates of change. It's the study of how functions change as their input values change. The key concept here is the **derivative**. Think of the derivative as the "slope" of a

function at any given point. It tells us how steep the graph of a function is at that exact moment, or how fast a quantity is changing.

Imagine you're driving a car. Your speed at any particular instant is the derivative of your position with respect to time. If your position function is  $s(t)$ , then your velocity (speed) is  $v(t) = s'(t)$ . This simple concept has profound implications across numerous fields.

## The Building Blocks: Understanding Derivatives

Before we tackle complex problems, let's revisit the fundamental ways we find derivatives. These are the tools in your calculus toolbox.

### 1. The Limit Definition of the Derivative

The formal definition of a derivative is based on limits. For a function  $f(x)$ , its derivative  $f'(x)$  is defined as:

$$f'(x) = \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h}$$

This might look intimidating, but it's essentially calculating the slope of a line segment between two points on the function's curve that are infinitesimally close together. While this definition is foundational, we often use shortcut rules for efficiency.

### 2. Differentiation Rules: Your Shortcut to Success

These rules are your best friends when solving differential calculus problems. Let's cover some of the most common ones:

- The Power Rule:** If  $f(x) = x^n$ , then  $f'(x) = nx^{n-1}$ . This is arguably the most frequently used rule.
- The Constant Rule:** If  $f(x) = c$  (where  $c$  is a constant), then  $f'(x) = 0$ . The slope of a horizontal line is always zero.
- The Constant Multiple Rule:** If  $f(x) = c \cdot g(x)$ , then  $f'(x) = c \cdot g'(x)$ . Constants just tag along for the ride.
- The Sum/Difference Rule:** If  $f(x) = g(x) \pm h(x)$ , then  $f'(x) = g'(x) \pm h'(x)$ . You can differentiate term by term.
- The Product Rule:** If  $f(x) = u(x) \cdot v(x)$ , then  $f'(x) = u'(x)v(x) + u(x)v'(x)$ . Remember "derivative of the first times the second, plus the first times the derivative of the second."
- The Quotient Rule:** If  $f(x) = \frac{u(x)}{v(x)}$ , then  $f'(x) = \frac{u'(x)v(x) - u(x)v'(x)}{(v(x))^2}$ . This one's a bit more complex: "low d-high minus high d-low, all over low squared."
- The Chain Rule:** This is crucial for differentiating composite functions (functions within functions). If  $y = f(u)$  and  $u = g(x)$ , then  $\frac{dy}{dx} = \frac{dy}{du} \cdot \frac{du}{dx}$ . In simpler terms, it's the derivative of the outer function (evaluated at the inner function) multiplied by the derivative of the inner function.
- Derivatives of Trigonometric Functions:** You'll need to know these like the back of your hand:
  - $\frac{d}{dx}(\sin x) = \cos x$
  - $\frac{d}{dx}(\cos x) = -\sin x$
  - $\frac{d}{dx}(\tan x) = \sec^2 x$
- Derivatives of Exponential and Logarithmic Functions:**
  - $\frac{d}{dx}(e^x) = e^x$
  - $\frac{d}{dx}(a^x) = a^x \ln a$
  - $\frac{d}{dx}(\ln x) = \frac{1}{x}$
  - $\frac{d}{dx}(\log_b x) = \frac{1}{x \ln b}$

# Common Differential Calculus Problems and Their Solutions

Now that we have our tools, let's see them in action with some typical problems. We'll walk through the thought process and steps to reach the solution.

## 1. Finding the Derivative of a Polynomial Function

**Problem:** Find the derivative of  $f(x) = 3x^4 - 5x^2 + 7x - 2$ .

**Solution:** This is a straightforward application of the Power Rule, Constant Multiple Rule, and Sum/Difference Rule.

- Differentiate term by term:** We'll find the derivative of each term separately.
- Apply the Power Rule:**
  - For  $3x^4$ :  $3 \cdot 4x^{4-1} = 12x^3$
  - For  $-5x^2$ :  $-5 \cdot 2x^{2-1} = -10x^1 = -10x$
  - For  $7x$  (which is  $7x^1$ ):  $7 \cdot 1x^{1-1} = 7x^0 = 7 \cdot 1 = 7$
  - For  $-2$  (a constant): The derivative is  $0$ .
- Combine the results:**  $f'(x) = 12x^3 - 10x + 7$ .

**Key takeaway:** Break down the polynomial and apply the power rule to each term.

## 2. Using the Product Rule

**Problem:** Find the derivative of  $f(x) = (x^3 + 2x)(5x^2 - 1)$ .

**Solution:** This function is a product of two simpler functions. Let  $u(x) = x^3 + 2x$  and  $v(x) = 5x^2 - 1$ .

- Find the derivatives of  $u(x)$  and  $v(x)$ :**
  - $u'(x) = 3x^2 + 2$  (using the Power Rule and Sum Rule)
  - $v'(x) = 10x$  (using the Power Rule and Constant Multiple Rule)
- Apply the Product Rule formula:**  $f'(x) = u'(x)v(x) + u(x)v'(x)$ .
- Substitute the parts:**  $f'(x) = (3x^2 + 2)(5x^2 - 1) + (x^3 + 2x)(10x)$ .
- Expand and simplify:**
  - $(3x^2 + 2)(5x^2 - 1) = 15x^4 - 3x^2 + 10x^2 - 2 = 15x^4 + 7x^2 - 2$
  - $(x^3 + 2x)(10x) = 10x^4 + 20x^2$
- Combine the expanded terms:**  $f'(x) = (15x^4 + 7x^2 - 2) + (10x^4 + 20x^2) = 25x^4 + 27x^2 - 2$ .

**Key takeaway:** Clearly identify the two functions being multiplied and then apply the product rule formula. Don't forget to simplify!

## 3. Applying the Quotient Rule

**Problem:** Find the derivative of  $f(x) = \frac{x^2 + 1}{x - 3}$ .

**Solution:** This is a classic case for the Quotient Rule. Let  $u(x) = x^2 + 1$  (the numerator) and  $v(x) = x - 3$  (the denominator).

- Find the derivatives of  $u(x)$  and  $v(x)$ :**
  - $u'(x) = 2x$
  - $v'(x) = 1$
- Apply the Quotient Rule formula:**  $f'(x) = \frac{u'(x)v(x) - u(x)v'(x)}{(v(x))^2}$ .
- Substitute the parts:**  $f'(x) = \frac{(2x)(x - 3) - (x^2 + 1)(1)}{(x - 3)^2}$ .

#### 4. Simplify the numerator:

1.  $(2x)(x - 3) = 2x^2 - 6x$

2.  $(x^2 + 1)(1) = x^2 + 1$

3. Numerator becomes:  $(2x^2 - 6x) - (x^2 + 1) = 2x^2 - 6x - x^2 - 1 = x^2 - 6x - 1$ .

5. **Write the final derivative:**  $f'(x) = \frac{x^2 - 6x - 1}{(x - 3)^2}$ .

**Key takeaway:** Be meticulous with the formula: "low d-high minus high d-low, all over low squared." Pay attention to signs when distributing.

## 4. Mastering the Chain Rule

**Problem:** Find the derivative of  $f(x) = (4x^3 - 5x)^7$ .

**Solution:** This is a composite function. The "outer" function is raising something to the power of 7, and the "inner" function is  $4x^3 - 5x$ . Let  $u = 4x^3 - 5x$ . Then  $f(x) = u^7$ .

1. **Differentiate the outer function with respect to  $u$ :**  $\frac{df}{du} = 7u^{7-1} = 7u^6$ .

2. **Differentiate the inner function with respect to  $x$ :**  $\frac{du}{dx} = 12x^2 - 5$ .

3. **Apply the Chain Rule:**  $\frac{df}{dx} = \frac{df}{du} \cdot \frac{du}{dx}$ .

4. **Substitute back  $u = 4x^3 - 5x$ :**  $f'(x) = 7(4x^3 - 5x)^6 \cdot (12x^2 - 5)$ .

5. **Rearrange for clarity:**  $f'(x) = 7(12x^2 - 5)(4x^3 - 5x)^6$ .

**Key takeaway:** Identify the inner and outer functions. Differentiate them separately and then multiply. Remember to substitute the inner function back into the derivative of the outer function.

## 5. Derivatives involving Trigonometric Functions

**Problem:** Find the derivative of  $g(x) = \sin(x^2 + 1)$ .

**Solution:** This is another chain rule problem. The outer function is  $\sin(\cdot)$  and the inner function is  $x^2 + 1$ . Let  $u = x^2 + 1$ . Then  $g(x) = \sin(u)$ .

1. **Differentiate the outer function with respect to  $u$ :**  $\frac{dg}{du} = \cos(u)$ .

2. **Differentiate the inner function with respect to  $x$ :**  $\frac{du}{dx} = 2x$ .

3. **Apply the Chain Rule:**  $\frac{dg}{dx} = \frac{dg}{du} \cdot \frac{du}{dx}$ .

4. **Substitute back  $u = x^2 + 1$ :**  $g'(x) = \cos(x^2 + 1) \cdot (2x)$ .

5. **Rearrange for clarity:**  $g'(x) = 2x \cos(x^2 + 1)$ .

**Key takeaway:** When differentiating trig functions with arguments that are not simply  $x$ , always suspect the chain rule.

## Applications of Differential Calculus: Beyond the Classroom

Why do we spend so much time learning these rules? Because differential calculus is incredibly practical. Here are just a few examples:

- Optimization Problems:** Finding the maximum or minimum value of a quantity (e.g., maximum profit, minimum cost, maximum area). This is where we set the derivative to zero and solve for critical points.
- Related Rates:** Problems where the rates of change of multiple related variables are involved (e.g., how fast is the radius of a balloon changing if its volume is increasing at a certain rate?).
- Curve Sketching:** Using the first and second derivatives to determine where a function is increasing/decreasing, its local maxima/minima, and its concavity.
- Physics:** Calculating velocity and acceleration from position functions, understanding forces, and modeling motion.

5. **Economics:** Analyzing marginal cost, marginal revenue, and profit maximization.
6. **Engineering:** Designing structures, optimizing processes, and analyzing system behavior.

## Optimization Problems: Finding the Best

One of the most powerful applications of differential calculus is finding maximum and minimum values. This is often done by:

1. **Formulating the function:** Express the quantity you want to maximize or minimize as a function of one variable.
2. **Finding the derivative:** Calculate the derivative of this function.
3. **Setting the derivative to zero:** Solve  $f'(x) = 0$  to find critical points.
4. **Using the First or Second Derivative Test:** Determine whether these critical points correspond to a maximum, minimum, or neither.

**Example:** A farmer wants to fence a rectangular field bordering a river. The farmer has 1000 meters of fencing. What are the dimensions of the field that will maximize the area?

**Solution Outline:**

1. Let the dimensions be  $l$  (length parallel to the river) and  $w$  (width perpendicular to the river).
2. Area  $A = l \cdot w$ .
3. Fencing constraint:  $l + 2w = 1000$  (one side is along the river, so it doesn't need fencing).
4. Express  $l$  in terms of  $w$ :  $l = 1000 - 2w$ .
5. Substitute into the area formula:  $A(w) = (1000 - 2w)w = 1000w - 2w^2$ .
6. Find the derivative:  $A'(w) = 1000 - 4w$ .
7. Set derivative to zero:  $1000 - 4w = 0 \implies 4w = 1000 \implies w = 250$  meters.
8. Find  $l$ :  $l = 1000 - 2(250) = 1000 - 500 = 500$  meters.
9. Using the second derivative test ( $A''(w) = -4$ , which is negative), this confirms it's a maximum.
10. The dimensions that maximize the area are 500 meters by 250 meters.

## Related Rates Problems: The Interconnectedness of Change

These problems are fun because they highlight how different rates of change are linked. The key is to implicitly differentiate the equation relating the variables with respect to time ( $t$ ).

**Example:** A ladder 10 feet long rests against a vertical wall. If the bottom of the ladder slides away from the wall at a rate of 1 ft/sec, how fast is the top of the ladder sliding down the wall when the bottom of the ladder is 6 feet from the wall?

**Solution Outline:**

1. Let  $x$  be the distance from the bottom of the ladder to the wall, and  $y$  be the height of the top of the ladder on the wall.
2. By Pythagorean theorem:  $x^2 + y^2 = 10^2 = 100$ .
3. We are given  $\frac{dx}{dt} = 1$  ft/sec.
4. We want to find  $\frac{dy}{dt}$  when  $x = 6$  feet.
5. Implicitly differentiate the equation with respect to  $t$ :  $2x \frac{dx}{dt} + 2y \frac{dy}{dt} = 0$ .
6. When  $x = 6$ , we need to find  $y$ . Using  $x^2 + y^2 = 100$ , we get  $6^2 + y^2 = 100 \implies 36 + y^2 = 100 \implies y^2 = 64 \implies y = 8$  feet.
7. Substitute known values into the differentiated equation:  $2(6)(1) + 2(8)\frac{dy}{dt} = 0$ .
8. Solve for  $\frac{dy}{dt}$ :  $12 + 16\frac{dy}{dt} = 0 \implies 16\frac{dy}{dt} = -12 \implies \frac{dy}{dt} = -\frac{12}{16} = -\frac{3}{4}$  ft/sec.

9. The top of the ladder is sliding down the wall at a rate of  $\frac{3}{4}$  ft/sec. The negative sign indicates it's moving downwards.

## The Foundation: Understanding Derivatives

At its heart, differential calculus is about the derivative. The derivative of a function at a specific point represents the instantaneous rate of change of that function at that point. Geometrically, it's the slope of the tangent line to the function's graph at that point. Understanding this fundamental concept is crucial for tackling any differential calculus problem.

### What is a Derivative?

Mathematically, the derivative of a function  $f(x)$ , denoted as  $f'(x)$  or  $\frac{dy}{dx}$ , is defined by the limit:

$$f'(x) = \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h}$$

This limit, if it exists, gives us the slope of the tangent line. The process of finding the derivative is called differentiation.

### Basic Differentiation Rules

While the limit definition is the formal basis, most problems are solved using a set of powerful differentiation rules. Mastering these rules is essential for efficient problem-solving in differential calculus.

1. **Power Rule:** If  $f(x) = x^n$ , then  $f'(x) = nx^{n-1}$ .
2. **Constant Multiple Rule:** If  $c$  is a constant, then  $\frac{d}{dx}[cf(x)] = c f'(x)$ .
3. **Sum and Difference Rule:**  $\frac{d}{dx}[f(x) \pm g(x)] = f'(x) \pm g'(x)$ .
4. **Product Rule:**  $\frac{d}{dx}[f(x)g(x)] = f'(x)g(x) + f(x)g'(x)$ .
5. **Quotient Rule:**  $\frac{d}{dx}\left[\frac{f(x)}{g(x)}\right] =$

$$\frac{f'(x)g(x) - f(x)g'(x)}{[g(x)]^2}.$$

6. Chain Rule: If  $y = f(u)$  and  $u = g(x)$ , then  $\frac{dy}{dx} = \frac{dy}{du} \cdot \frac{du}{dx}$ . This rule is paramount for differentiating composite functions.

7. Derivatives of Trigonometric Functions:  $\frac{d}{dx}(\sin x) = \cos x$ ,  $\frac{d}{dx}(\cos x) = -\sin x$ , etc.

8. Derivatives of Exponential and Logarithmic Functions:  $\frac{d}{dx}(e^x) = e^x$ ,  $\frac{d}{dx}(\ln x) = \frac{1}{x}$ .

## Common Differential Calculus Problems and Their Solutions

The ability to apply these rules to various scenarios is key to solving differential calculus problems. Let's explore some common categories of problems and break down their solutions.

### 1. Finding the Derivative of Various Functions

This is the most fundamental type of problem. It tests your understanding and application of the basic differentiation rules.

#### Example 1: Polynomial Function

**Problem:** Find the derivative of  $f(x) = 3x^4 - 5x^2 + 7x - 1$ .

**Solution:** We apply the power rule and sum/difference rule.

$$f'(x) = \frac{d}{dx}(3x^4) - \frac{d}{dx}(5x^2) + \frac{d}{dx}(7x) - \frac{d}{dx}(1)$$

$$f'(x) = 3(4x^{4-1}) - 5(2x^{2-1}) + 7(1x^{1-1}) - 0$$

$$f'(x) = 12x^3 - 10x + 7.$$

**Analysis:** This demonstrates a straightforward application of the power rule and the constant multiple rule. The derivative of a

constant is always zero.

## Example 2: Rational Function

**Problem:** Find the derivative of  $g(x) = \frac{x^2 + 1}{x - 2}$ .

**Solution:** We use the quotient rule, where  $f(x) = x^2 + 1$  and  $h(x) = x - 2$ .

First, find the derivatives of the numerator and denominator:  $f'(x) = 2x$  and  $h'(x) = 1$ .

Applying the quotient rule:  $g'(x) = \frac{f'(x)h(x) - f(x)h'(x)}{[h(x)]^2}$

$$g'(x) = \frac{(2x)(x - 2) - (x^2 + 1)(1)}{(x - 2)^2}$$

$$g'(x) = \frac{2x^2 - 4x - x^2 - 1}{(x - 2)^2}$$

$$g'(x) = \frac{x^2 - 4x - 1}{(x - 2)^2}.$$

**Analysis:** The quotient rule requires careful algebraic manipulation to simplify the numerator. Errors often arise from sign mistakes or incorrect application of the formula.

## Example 3: Composite Function (Chain Rule)

**Problem:** Find the derivative of  $y = (\sin(x^3))^2$ .

**Solution:** This problem requires the chain rule. Let  $u = \sin(x^3)$  and  $y = u^2$ .

First, find  $\frac{dy}{du} = 2u$ .

Next, we need to find the derivative of  $u = \sin(x^3)$ . This itself requires the chain rule. Let  $v = x^3$ , so  $u = \sin(v)$ .

Then  $\frac{du}{dv} = \cos(v)$  and  $\frac{dv}{dx} = 3x^2$ .

So,  $\frac{du}{dx} = \frac{du}{dv} \cdot \frac{dv}{dx} = \cos(v) \cdot 3x^2 = \cos(x^3) \cdot 3x^2$ .

Now, back to finding  $\frac{dy}{dx}$  using the main chain rule:

$$\frac{dy}{dx} = \frac{dy}{du} \cdot \frac{du}{dx}.$$

Substitute  $u = \sin(x^3)$ :  $\frac{dy}{dx} = (2u) \cdot (3x^2 \cos(x^3))$

$$\frac{dy}{dx} = 2(\sin(x^3)) \cdot (3x^2 \cos(x^3))$$

$$\frac{dy}{dx} = 6x^2 \sin(x^3) \cos(x^3).$$

**Analysis:** The chain rule is a fundamental concept in differential calculus. For nested functions, you differentiate from the outside in, multiplying the derivatives at each step. Recognizing the 'inner' and 'outer' functions is crucial.

## 2. Applications of Derivatives: Rate of Change

Derivatives are inherently about rates of change. These problems involve interpreting the derivative in a real-world context.

### Example 4: Velocity and Acceleration

**Problem:** The position of a particle moving along a straight line is given by  $s(t) = t^3 - 6t^2 + 9t$ , where  $s$  is in meters and  $t$  is in seconds. Find the velocity and acceleration of the particle at  $t = 2$  seconds.

**Solution:** Velocity  $v(t)$  is the first derivative of position  $s(t)$  with respect to time.

$$v(t) = s'(t) = \frac{d}{dt}(t^3 - 6t^2 + 9t)$$

$$v(t) = 3t^2 - 12t + 9.$$

At  $t = 2$ ,  $v(2) = 3(2)^2 - 12(2) + 9 = 3(4) - 24 + 9 = 12 - 24 + 9 = -3$  m/s.

Acceleration  $a(t)$  is the first derivative of velocity  $v(t)$  (or the second derivative of position  $s(t)$ ).

$$a(t) = v'(t) = s''(t) = \frac{d}{dt}(3t^2 - 12t + 9)$$

$$a(t) = 6t - 12.$$

At  $t = 2$ ,  $a(2) = 6(2) - 12 = 12 - 12 = 0$  m/s<sup>2</sup>.

**Analysis:** This problem highlights how derivatives model physical quantities. A negative velocity indicates movement in the negative direction. Zero acceleration means the velocity is not changing at that instant.

### 3. Optimization Problems

Optimization problems involve finding the maximum or minimum value of a function, often within a given constraint. This is where differential calculus truly shines in practical applications.

#### Key Concepts for Optimization:

- 1. Critical Points:** Points where the derivative is zero or undefined. These are candidates for local maxima or minima.
- 2. First Derivative Test:** Examining the sign of the derivative to the left and right of a critical point to determine if it's a local max, min, or neither.
- 3. Second Derivative Test:** Using the second derivative to classify critical points (concave up for min, concave down for max).
- 4. Extreme Value Theorem:** For a continuous function on a closed interval, absolute maximum and minimum values exist and

occur at critical points or endpoints.

### Example 5: Maximizing Area

**Problem:** A farmer has 2400 feet of fencing and wants to fence off a rectangular field that borders a straight river. He needs no fence along the river. What are the dimensions of the field that has the largest area?

**Solution:** Let the width of the field perpendicular to the river be  $w$  and the length parallel to the river be  $l$ . The perimeter constraint is  $2w + l = 2400$ , so  $l = 2400 - 2w$ .

The area  $A$  is given by  $A = l \cdot w$ . Substitute  $l$ :  $A(w) = (2400 - 2w)w = 2400w - 2w^2$ .

To maximize the area, we find the critical points by taking the derivative of  $A(w)$  with respect to  $w$  and setting it to zero.

$$A'(w) = 2400 - 4w.$$

Set  $A'(w) = 0$ :  $2400 - 4w = 0 \implies 4w = 2400 \implies w = 600$  feet.

Now find the corresponding length:  $l = 2400 - 2(600) = 2400 - 1200 = 1200$  feet.

To confirm this is a maximum, we can use the second derivative test:  $A''(w) = -4$ . Since  $A''(600) = -4 < 0$ , this indicates a local maximum.

**Analysis:** This is a classic optimization problem. The process involves setting up a function to be optimized (area) and a constraint equation (fencing), then using calculus to find the extreme value.

#### 4. Related Rates Problems

Related rates problems deal with situations where multiple quantities are changing with time, and the rate of change of one quantity is related to the rate of change of others. The chain rule is fundamental here.

##### Example 6: Expanding Balloon

**Problem:** Air is being pumped into a spherical balloon at a rate of  $100 \text{ cm}^3/\text{s}$ . How fast is the radius of the balloon increasing when the diameter is 50 cm?

**Solution:** The volume  $V$  of a sphere is given by  $V = \frac{4}{3}\pi r^3$ . We are given  $\frac{dV}{dt} = 100 \text{ cm}^3/\text{s}$  and we want to find  $\frac{dr}{dt}$  when the diameter is 50 cm (so the radius  $r = 25 \text{ cm}$ ).

Differentiate both sides of the volume equation with respect to time  $t$  using the chain rule:

$$\frac{dV}{dt} = \frac{d}{dt} \left( \frac{4}{3}\pi r^3 \right)$$

$$\frac{dV}{dt} = \frac{4}{3}\pi \cdot 3r^2 \cdot \frac{dr}{dt}$$

$$\frac{dV}{dt} = 4\pi r^2 \frac{dr}{dt}.$$

Now, plug in the given values:  $100 = 4\pi (25)^2 \frac{dr}{dt}$ .

$$100 = 4\pi (625) \frac{dr}{dt}$$

$$100 = 2500\pi \frac{dr}{dt}.$$

Solve for  $\frac{dr}{dt}$ :  $\frac{dr}{dt} = \frac{100}{2500\pi} = \frac{1}{25\pi} \text{ cm/s}$ .

**Analysis:** The key to related rates problems is to identify the

variables, their rates of change, and the equation that connects them. Then, differentiate implicitly with respect to time.

## 5. Curve Sketching and Analysis

Differential calculus provides powerful tools for understanding the behavior of a function and sketching its graph. This involves analyzing:

1. **First Derivative:** Intervals of increase and decrease, local maxima and minima.
2. **Second Derivative:** Intervals of concavity, inflection points.
3. **Intercepts, Asymptotes, and Domain/Range:** These are found using algebraic methods, but calculus helps interpret their behavior.

### Example 7: Analyzing a Cubic Function

**Problem:** Analyze the function  $f(x) = x^3 - 3x^2$  for intervals of increase/decrease, local extrema, and concavity.

**Solution:**

1. **Domain:** All real numbers ( $\mathbb{R}$ ).
2. **First Derivative** (for increase/decrease and extrema):

$$f'(x) = 3x^2 - 6x = 3x(x - 2).$$

Critical points are where  $f'(x) = 0$ :  $x = 0$  and  $x = 2$ .

**Test intervals:**

1.  $x < 0$ :  $f'(-1) = 3(-1)(-1-2) = 3 > 0$  (Increasing)
2.  $0 < x < 2$ :  $f'(1) = 3(1)(1-2) = -3 < 0$  (Decreasing)
3.  $x > 2$ :  $f'(3) = 3(3)(3-2) = 9 > 0$  (Increasing)

**Local Maximum at  $x=0$ :  $f(0) = 0^3 - 3(0)^2 = 0$ . Point:  $(0, 0)$ .**

**Local Minimum at  $x=2$ :  $f(2) = 2^3 - 3(2)^2 = 8 - 12 = -4$ . Point:  $(2, -4)$ .**

**3. Second Derivative (for concavity and inflection points):**

$$f''(x) = 6x - 6 = 6(x - 1).$$

**Possible inflection points where  $f''(x) = 0$ :  $x = 1$ .**

**Test intervals:**

**1.  $x < 1$ :  $f''(0) = 6(0) - 6 = -6 < 0$  (Concave Down)**

**2.  $x > 1$ :  $f''(2) = 6(2) - 6 = 6 > 0$  (Concave Up)**

**Inflection Point at  $x=1$ :  $f(1) = 1^3 - 3(1)^2 = 1 - 3 = -2$ . Point:  $(1, -2)$ .**

**Analysis: By systematically analyzing the first and second derivatives, we can determine the shape of the curve, identifying where it rises, falls, and changes its curvature.**

## **Strategies for Success in Differential Calculus Problems**

**Tackling differential calculus problems effectively requires a combination of theoretical understanding and practical strategies:**

- 1. Master the Fundamentals: Ensure a solid grasp of the limit definition and all basic differentiation rules. Practice them until they become second nature.**
- 2. Understand the Problem Statement: Carefully read and re-read the problem. Identify what is being asked, what information is given, and what quantities are changing.**
- 3. Visualize: For geometric or applied problems, drawing a diagram can be immensely helpful in understanding the relationships**

between variables.

4. **Break Down Complex Problems:** For problems involving multiple steps or nested functions (like the chain rule), break them down into smaller, manageable parts.
5. **Use Proper Notation:** Consistent and correct notation (e.g.,  $f'(x)$ ,  $\frac{dy}{dx}$ ) helps in tracking your work and avoiding errors.
6. **Practice Regularly:** The more you practice, the more familiar you will become with different problem types and solution techniques.
7. **Review and Understand Solutions:** Don't just solve problems; take the time to understand *why* a particular solution method works. Analyze the steps and the reasoning behind them.
8. **Check Your Work:** For optimization and related rates problems, ensure your answer makes sense in the context of the problem. For derivative calculations, you can sometimes use numerical approximations or differentiation calculators as a check (but always aim to solve it yourself first).
9. **Seek Help When Needed:** If you're stuck on a concept or a problem, don't hesitate to ask your instructor, a tutor, or collaborate with classmates.

## Questions & Answers About differential calculus problems and solutions

| No | Question                                                                               | Answer                                                                                                                                                                                                                                                                                                                                 |
|----|----------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1  | How can I quickly find the rate of change of a function in differential calculus?      | The rate of change of a function is its derivative! For a function $f(x)$ , its derivative $f'(x)$ tells you the instantaneous slope of the tangent line at any point $x$ , which represents how $f(x)$ changes with respect to $x$ . Common techniques include power rule, product rule, quotient rule, and chain rule.               |
| 2  | What's the deal with optimization problems in differential calculus? How do they work? | Optimization problems use derivatives to find maximum or minimum values of a function. You typically find the derivative of the function, set it equal to zero to find critical points, and then use the second derivative test or analyze the sign changes of the first derivative to determine if these points are maxima or minima. |

|   |                                                                                                     |                                                                                                                                                                                                                                                                                                                                                                                                               |
|---|-----------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3 | I keep messing up the chain rule. What's a good way to approach chain rule problems?                | The chain rule is for differentiating composite functions (functions within functions). Think of it as 'outside' derivative times 'inside' derivative. Identify the 'outer' function and its derivative, then identify the 'inner' function and its derivative, and multiply them together. For example, $d/dx [f(g(x))] = f'(g(x)) * g'(x)$ .                                                                |
| 4 | What's the geometric interpretation of the derivative, and why is it important?                     | Geometrically, the derivative of a function at a point represents the slope of the tangent line to the function's graph at that point. This is crucial because it tells us the instantaneous rate at which the function's output is changing relative to its input. It's fundamental to understanding curves, motion, and rates of change in real-world applications.                                         |
| 5 | How do implicit differentiation problems differ from regular differentiation, and what's the trick? | Implicit differentiation is used when a relationship between x and y is given implicitly (e.g., $x^2 + y^2 = 25$ ), not explicitly as $y = f(x)$ . The trick is to differentiate both sides of the equation with respect to x, remembering to treat y as a function of x and apply the chain rule whenever you differentiate a term involving y (e.g., $d/dx(y^2) = 2y * dy/dx$ ). Then, you solve for dy/dx. |
