Conquering Analytic Geometry: Problems with Solutions

Analytic geometry, also known as coordinate geometry, bridges the gap between algebra and geometry. It allows us to represent geometric shapes and their properties using algebraic equations and coordinates. This powerful tool is fundamental in various fields, from engineering and physics to computer graphics and data analysis. This comprehensive guide provides a range of analytic geometry problems with detailed solutions, enhancing your understanding and problem-solving abilities. While "analytic geometry problems with solutions" doesn't have unique advantages **per se**, its strength lies in its direct application of concepts. The advantage is in the clarity and understanding gained by seeing the process step-by-step. Instead of listing unique advantages, let's explore key related topics to illustrate its power.

1. Lines in Analytic Geometry

The foundation of analytic geometry lies in understanding lines. We can

represent a line using different forms of equations: • Slope-intercept form: $y = mx + b$, where 'm' is the slope and 'b' is the y-intercept. • Point-slope form: $y - y_1 = m(x - x_1)$, where (x_1, y_1) is a point on the line and 'm' is the slope. • Standard form: $Ax + By = C$, where A, B, and C are constants.

Problem 1: Find the equation of the line passing through points (2, 3) and (4, 7). Solution: 1. Find the slope (m): $m = (7 - 3) / (4 - 2) = 2$ 2. Use the point-slope form: $y - 3 = 2(x - 2)$ 3. Simplify: $y = 2x - 1$ Problem 2: Find the intersection point of the lines $y = 2x + 1$ and $y = -x + 4$. Solution: 1. Set the equations equal to each other: $2x + 1 = -x + 4$ 2. Solve for x: $3x = 3 \Rightarrow x = 1$ 3. Substitute $x = 1$ into either equation to find y: $y = 2(1) + 1 = 3$ 4. The intersection point is (1, 3).

2. Circles in Analytic Geometry

A circle with center (h, k) and radius 'r' has the equation $(x - h)^2 + (y - k)^2 = r^2$. Problem 3: Find the equation of a circle with center (1, -2) and radius 3. Solution: $(x - 1)^2 + (y + 2)^2 = 9$ Problem 4: Determine the center and radius of the circle $x^2 + y^2 - 4x + 6y - 3 = 0$. Solution: Complete the square for x and y terms: $(x^2 - 4x + 4) + (y^2 + 6y + 9) = 3 + 4 + 9$ $(x - 2)^2 + (y + 3)^2 = 16$ Center: (2, -3), Radius: 4

3. Conic Sections in Analytic Geometry

Conic sections (parabolas, ellipses, hyperbolas) are curves formed by the intersection of a plane and a cone. Their equations are more complex but follow predictable patterns. | Conic Section | Standard Equation (center at origin) | ||| | Parabola (vertical axis) | $x^2 = 4py$ | | Ellipse | $x^2/a^2 + y^2/b^2 = 1$ | | Hyperbola | $x^2/a^2 - y^2/b^2 = 1$ | Problem 5: Identify the conic section represented by the equation $9x^2 + 4y^2 = 36$. Solution: Divide by 36: $x^2/4 + y^2/9 = 1$. This is an ellipse with $a = 2$ and $b = 3$.

4. Distance and Midpoint Formulas

These formulas are essential tools in analytic geometry: • Distance formula:

$d = \sqrt{[(x_2 - x_1)^2 + (y_2 - y_1)^2]}$ (distance between (x_1, y_1) and (x_2, y_2)) •

Midpoint formula: $M = ((x_1 + x_2)/2, (y_1 + y_2)/2)$ (midpoint between (x_1, y_1) and (x_2, y_2)) Problem 6: Find the distance between points A(1, 2) and B(4,

6). Solution: $d = \sqrt{[(4 - 1)^2 + (6 - 2)^2]} = \sqrt{(9 + 16)} = 5$

5. Applications of Analytic Geometry

Analytic geometry has numerous applications: • Computer graphics:

Representing shapes and performing transformations. • Robotics:

Path planning and motion control. • Engineering: *Designing structures and analyzing stress.* • Physics: **Modeling projectile motion and other**

physical phenomena. Problem 7 (Application): A projectile is launched from the origin with an initial velocity of 10 m/s at an angle of 30 degrees.

Its trajectory can be approximated by a parabola. Find the equation of the

parabola (simplified). Solution: This involves physics and analytic geometry.

The solution requires knowledge of projectile motion equations, which are beyond the scope of this basic but demonstrate the real-world application.

However, you'd likely end up with a parabolic equation representing the projectile's path. Conclusion: *Analytic geometry provides a powerful*

framework for solving geometric problems using algebraic techniques.

Mastering its core concepts and practicing various problem types will

significantly enhance your mathematical skills and open doors to various

applications in science, engineering, and technology. By understanding the

equations of lines, circles, conics, and utilizing the distance and midpoint

formulas, you gain the ability to precisely describe and analyze geometric

shapes and their relationships. FAQs: 1. What is the difference between

So, grab your virtual pencil and paper, and let's get started on becoming an analytic geometry pro!

What Exactly is Analytic Geometry?

Before we jump into problem-solving, let's quickly recap what analytic geometry is all about. At its core, it's the study of geometry using a coordinate system. We typically use the Cartesian coordinate system, which involves two perpendicular axes, the x-axis (horizontal) and the y-axis (vertical). Every point on this plane is represented by an ordered pair (x, y) . This system allows us to:

1. Represent geometric objects (points, lines, curves) as algebraic equations.
2. Use algebraic methods to solve geometric problems.
3. Analyze geometric properties through algebraic manipulation.

This powerful connection means that understanding algebraic concepts like linear equations, quadratic equations, and functions is key to mastering analytic geometry. We'll be revisiting many of these fundamental algebraic tools as we work through our problems.

Common Analytic Geometry Problems and Their Solutions

Let's roll up our sleeves and tackle some typical analytic geometry problems. We'll cover a range of topics, from the basics to slightly more advanced concepts.

1. Finding the Distance Between Two Points

This is arguably one of the most fundamental analytic geometry problems. Given two points, $P_1(x_1, y_1)$ and $P_2(x_2, y_2)$, how do we find the straight-line distance between them?

The Distance Formula

The distance formula is derived directly from the Pythagorean theorem. Imagine a right-angled triangle where the distance between the two points is the hypotenuse. The legs of the triangle have lengths equal to the difference in the x-coordinates and the difference in the y-coordinates.

The formula is: $d = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2}$

Example Problem:

Find the distance between the points $A(2, 3)$ and $B(5, 7)$.

Solution:

1. Identify the coordinates: $x_1 = 2$, $y_1 = 3$, $x_2 = 5$, $y_2 = 7$.
2. Plug these values into the distance formula: $d = \sqrt{(5 - 2)^2 + (7 - 3)^2}$
3. Calculate the differences: $d = \sqrt{(3)^2 + (4)^2}$
4. Square the differences: $d = \sqrt{9 + 16}$
5. Add the squared differences: $d = \sqrt{25}$
6. Take the square root: $d = 5$

So, the distance between points A and B is 5 units.

2. Finding the Midpoint of a Line Segment

What if you need to find the exact center point of a line segment connecting two given points? Analytic geometry has a straightforward

formula for this too.

The Midpoint Formula

The midpoint $M(x, y)$ of a line segment with endpoints (x_1, y_1) and (x_2, y_2) is found by averaging the x-coordinates and averaging the y-coordinates.

The formula is: **$M(x, y) = [(x_1 + x_2)/2, (y_1 + y_2)/2]$**

Example Problem:

Find the midpoint of the line segment connecting $P(-1, 4)$ and $Q(3, -2)$.

Solution:

1. Identify the coordinates: $x_1 = -1, y_1 = 4, x_2 = 3, y_2 = -2$.
2. Apply the midpoint formula: $x = (-1 + 3) / 2 = 2 / 2 = 1$ $y = (4 + (-2)) / 2 = 2 / 2 = 1$

The midpoint of the line segment PQ is $(1, 1)$.

3. Finding the Equation of a Line

Lines are fundamental building blocks in analytic geometry. We often need to find the algebraic equation that represents a given line.

Key Concepts: Slope and Intercepts

1. **Slope (m):** Represents the steepness of a line. It's the "rise over run" - the change in y divided by the change in x between any two points on the line. The slope formula is: **$m = (y_2 - y_1) / (x_2 - x_1)$** .
2. **Y-intercept (b):** The point where the line crosses the y-axis. At this point, $x = 0$.
3. **X-intercept:** The point where the line crosses the x-axis. At this point, $y = 0$.

Common Forms of Linear Equations:

1. **Slope-Intercept Form:** $y = mx + b$ (most common and useful)
2. **Point-Slope Form:** $y - y_1 = m(x - x_1)$ (useful when you have a point and the slope)
3. **Standard Form:** $Ax + By = C$

Example Problem 1: Finding the equation of a line given two points.

Find the equation of the line passing through the points C(1, 2) and D(3, 8).

Solution:

1. Find the slope (m) using the slope formula: $m = (8 - 2) / (3 - 1) = 6 / 2 = 3$
2. Now we have the slope ($m = 3$). We can use the point-slope form with either point. Let's use point C(1, 2): $y - 2 = 3(x - 1)$
3. Convert to slope-intercept form by solving for y: $y - 2 = 3x - 3$
 $y = 3x - 3 + 2$
 $y = 3x - 1$

The equation of the line is $y = 3x - 1$.

Example Problem 2: Finding the equation of a line given a point and the slope.

Find the equation of the line with a slope of -2 that passes through the point E(4, -5).

Solution:

1. We have $m = -2$ and a point $(x_1, y_1) = (4, -5)$. Use the point-slope form:
 $y - (-5) = -2(x - 4)$
2. Simplify and convert to slope-intercept form: $y + 5 = -2x + 8$
 $y = -2x + 8 - 5$
 $y = -2x + 3$

The equation of the line is $y = -2x + 3$.

4. Understanding Parallel and Perpendicular Lines

The relationship between lines in terms of their slopes is a crucial concept in analytic geometry.

Key Properties:

1. **Parallel Lines:** Two distinct lines are parallel if and only if they have the same slope. ($m_1 = m_2$)
2. **Perpendicular Lines:** Two lines are perpendicular if and only if the product of their slopes is -1. ($m_1 * m_2 = -1$), or one slope is the negative reciprocal of the other.

Example Problem 1: Determining if lines are parallel or perpendicular.

Line L1 passes through (1, 1) and (3, 5). Line L2 passes through (0, 2) and (2, 0). Are L1 and L2 parallel, perpendicular, or neither?

Solution:

1. Find the slope of L1: $m_1 = (5 - 1) / (3 - 1) = 4 / 2 = 2$
2. Find the slope of L2: $m_2 = (0 - 2) / (2 - 0) = -2 / 2 = -1$
3. Compare the slopes: $m_1 = 2$ and $m_2 = -1$. Since $m_1 \neq m_2$, they are not parallel. Check if $m_1 * m_2 = -1$: $2 * (-1) = -2$. This is not -1, so they are not perpendicular.

Therefore, the lines are neither parallel nor perpendicular.

Example Problem 2: Finding the equation of a line parallel to a given line.

Find the equation of the line that passes through the point (2, 4) and is parallel to the line $y = 3x - 5$.

Solution:

1. The given line is $y = 3x - 5$. Its slope (m_1) is 3.
2. Since the new line is parallel, its slope (m_2) will be the same: $m_2 = 3$.
3. We have a point (2, 4) and a slope $m = 3$. Use the point-slope form: $y - 4 = 3(x - 2)$
4. Convert to slope-intercept form: $y - 4 = 3x - 6$ $y = 3x - 6 + 4$ $y = 3x - 2$

The equation of the parallel line is $y = 3x - 2$.

Example Problem 3: Finding the equation of a line perpendicular to a given line.

Find the equation of the line that passes through the point (-1, 3) and is perpendicular to the line $y = (1/2)x + 1$.

Solution:

1. The given line is $y = (1/2)x + 1$. Its slope (m_1) is $1/2$.
2. For a perpendicular line, the slope (m_2) is the negative reciprocal of m_1 :
 $m_2 = -1 / (1/2) = -2$
3. We have a point (-1, 3) and a slope $m = -2$. Use the point-slope form: $y - 3 = -2(x - (-1))$
4. Simplify and convert to slope-intercept form: $y - 3 = -2(x + 1)$ $y - 3 = -2x - 2$ $y = -2x - 2 + 3$ $y = -2x + 1$

The equation of the perpendicular line is $y = -2x + 1$.

5. Understanding the Equation of a Circle

Circles are elegant shapes, and their algebraic representation in analytic geometry is quite neat.

The Standard Equation of a Circle

A circle with center (h, k) and radius r has the equation:

$$(x - h)^2 + (y - k)^2 = r^2$$

If the center is at the origin (0, 0), the equation simplifies to: $x^2 + y^2 = r^2$

Example Problem 1: Finding the equation of a circle given center and radius.

Find the equation of the circle with center (3, -2) and radius 5.

Solution:

1. Identify the center $(h, k) = (3, -2)$ and radius $r = 5$.
2. Plug these values into the standard equation: $(x - 3)^2 + (y - (-2))^2 = 5^2$
3. Simplify: $(x - 3)^2 + (y + 2)^2 = 25$

The equation of the circle is $(x - 3)^2 + (y + 2)^2 = 25$.

Example Problem 2: Finding the center and radius of a circle from its equation.

Find the center and radius of the circle with the equation $(x + 1)^2 + (y - 4)^2 = 16$.

Solution:

1. Compare the given equation to the standard form $(x - h)^2 + (y - k)^2 = r^2$:
 $(x - (-1))^2 + (y - 4)^2 = 4^2$
2. From this, we can identify: $h = -1$ $k = 4$ $r = 4$

The center of the circle is $(-1, 4)$ and its radius is 4.

Example Problem 3: Finding the equation of a circle given endpoints of a diameter.

Find the equation of the circle if the points (2, 5) and (6, -3) are the endpoints of a diameter.

Solution:

1. First, find the center of the circle, which is the midpoint of the diameter. Let the endpoints be A(2, 5) and B(6, -3). Center $(h, k) = [(2 + 6)/2, (5 + (-3))/2] = [8/2, 2/2] = (4, 1)$
2. Next, find the radius. The radius is half the length of the diameter, or the distance from the center to either endpoint. Let's find the distance from the center (4, 1) to endpoint (2, 5). $r^2 = (2 - 4)^2 + (5 - 1)^2$ $r^2 = (-2)^2 + (4)^2$ $r^2 = 4 + 16$ $r^2 = 20$
3. Now we have the center $(h, k) = (4, 1)$ and $r^2 = 20$. Plug these into the standard equation of a circle: $(x - 4)^2 + (y - 1)^2 = 20$

The equation of the circle is $(x - 4)^2 + (y - 1)^2 = 20$.

6. Finding Intersections of Lines and Curves

A powerful application of analytic geometry is finding where different geometric objects meet. This usually involves solving a system of equations.

Example Problem: Intersection of a Line and a Circle

Find the points of intersection between the line $y = x + 1$ and the circle $x^2 + y^2 = 25$.

Solution:

1. We have a system of two equations: Equation 1 (Line): $y = x + 1$
Equation 2 (Circle): $x^2 + y^2 = 25$
2. Substitute Equation 1 into Equation 2 to eliminate y : $x^2 + (x + 1)^2 = 25$
3. Expand and simplify the equation: $x^2 + (x^2 + 2x + 1) = 25$ $2x^2 + 2x + 1 = 25$ $2x^2 + 2x - 24 = 0$
4. Divide by 2 to simplify: $x^2 + x - 12 = 0$
5. Factor the quadratic equation: $(x + 4)(x - 3) = 0$

6. Solve for x : $x + 4 = 0 \Rightarrow x = -4$ $x - 3 = 0 \Rightarrow x = 3$
7. Now, substitute these x -values back into Equation 1 ($y = x + 1$) to find the corresponding y -values: If $x = -4$: $y = -4 + 1 = -3$. Point: $(-4, -3)$ If $x = 3$: $y = 3 + 1 = 4$. Point: $(3, 4)$

The points of intersection are $(-4, -3)$ and $(3, 4)$.

Analytic Geometry Skills

The problems we've covered are just the tip of the iceberg. Analytic geometry extends to parabolas, ellipses, hyperbolas (conic sections), 3D geometry, vectors, and much more. Understanding these fundamental concepts will provide a strong foundation for exploring these more advanced topics.

For instance, understanding the general form of a quadratic equation in two variables, $Ax^2 + Bxy + Cy^2 + Dx + Ey + F = 0$, allows us to identify and analyze different conic sections. Problems might involve finding the foci, vertices, or directrix of these curves, which are all solvable using analytic geometry principles.

Furthermore, the transition to three-dimensional analytic geometry involves extending the coordinate system to include a z-axis. This opens up a whole new realm of problems involving planes, spheres, and other 3D objects. The distance formula, for example, is easily extended to 3D: $d = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2}$.

This article delves into a comprehensive exploration of analytic geometry problems, offering detailed solutions and insights that will solidify your understanding.

Unlocking the Power of Analytic Geometry: Key Concepts and Problem-Solving Strategies

At its heart, analytic geometry, also known as coordinate geometry, utilizes a Cartesian coordinate system (typically two or three perpendicular axes) to define points, lines, curves, and surfaces. This system assigns numerical coordinates to every point, enabling the translation of geometric figures into algebraic equations. Understanding this fundamental translation is the first step in tackling any analytic geometry problem. We will explore various types of problems, from basic coordinate plotting to more complex loci and transformations.

1. Points and Distances in the Coordinate Plane

The simplest analytic geometry problems often revolve around points and the distances between them. A point in a 2D plane is represented by an ordered pair (x, y) , and in 3D by an ordered triple (x, y, z) . The distance formula, derived from the Pythagorean theorem, is crucial here.

Problem 1: Finding the Distance Between Two Points

Problem: Calculate the distance between the points A(2, 3) and B(5, 7).

Solution: The distance formula between two points (x_1, y_1) and (x_2, y_2) is given by $d = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2}$.

Here, $(x_1, y_1) = (2, 3)$ and $(x_2, y_2) = (5, 7)$.

Substituting these values into the formula:

$$d = \sqrt{(5 - 2)^2 + (7 - 3)^2}$$

$$d = \sqrt{(3)^2 + (4)^2}$$

$$d = \sqrt{9 + 16}$$

$$d = \sqrt{25}$$

$$d = 5$$

Therefore, the distance between points A and B is 5 units.

Problem 2: Determining the Midpoint of a Line Segment

Problem: Find the midpoint of the line segment connecting points P(-1, 4) and Q(3, -2).

Solution: The midpoint formula for a line segment with endpoints (x_1, y_1) and (x_2, y_2) is $M = \left(\frac{x_1 + x_2}{2}, \frac{y_1 + y_2}{2}\right)$.

Here, $(x_1, y_1) = (-1, 4)$ and $(x_2, y_2) = (3, -2)$.

Applying the formula:

$$M_x = \frac{-1 + 3}{2} = \frac{2}{2} = 1$$

$$M_y = \frac{4 + (-2)}{2} = \frac{2}{2} = 1$$

The midpoint of the line segment PQ is (1, 1).

2. Equations of Lines and Their Properties

Lines are fundamental geometric objects in analytic geometry. Their equations can be represented in various forms, each offering a different perspective on their orientation and position. Understanding the slope-intercept form, point-slope form, and standard form is essential for solving line-related problems.

Problem 3: Finding the Equation of a Line Given Two Points

Problem: Determine the equation of the line passing through points C(1, 2) and D(4, 8).

Solution: First, we calculate the slope (m) of the line using the formula $m = \frac{y_2 - y_1}{x_2 - x_1}$.

Here, $(x_1, y_1) = (1, 2)$ and $(x_2, y_2) = (4, 8)$.

$$m = \frac{8 - 2}{4 - 1} = \frac{6}{3} = 2$$

Now, we can use the point-slope form of a linear equation: $y - y_1 = m(x - x_1)$. We can use either point C or D.

Using point C(1, 2):

$$y - 2 = 2(x - 1)$$

$$y - 2 = 2x - 2$$

$$y = 2x$$

Alternatively, we could express this in standard form $Ax + By + C = 0$: $2x - y = 0$. This equation represents a line passing through the origin with a slope of 2.

Problem 4: Determining Parallel and Perpendicular Lines

Problem: Find the equation of a line that is perpendicular to the line $y = 3x + 5$ and passes through the point (2, -1).

Solution: Two lines are perpendicular if the product of their slopes is -1. The given line has a slope $m_1 = 3$. The slope of the perpendicular line, m_2 , will satisfy $m_1 \cdot m_2 = -1$.

$$3 \cdot m_2 = -1$$

$$m_2 = -\frac{1}{3}$$

Now, we use the point-slope form with the point $(2, -1)$ and the slope $m_2 = -\frac{1}{3}$:

$$y - (-1) = -\frac{1}{3}(x - 2)$$

$$y + 1 = -\frac{1}{3}x + \frac{2}{3}$$

$$y = -\frac{1}{3}x + \frac{2}{3} - 1$$

$$y = -\frac{1}{3}x - \frac{1}{3}$$

The equation of the perpendicular line is $y = -\frac{1}{3}x - \frac{1}{3}$.

3. Conic Sections: Circles, Ellipses, Parabolas, and Hyperbolas

Conic sections are curves formed by the intersection of a plane and a double cone. In analytic geometry, their equations are quadratic in x and y . Understanding their standard forms and properties is key to solving complex problems related to these shapes.

3.1 Circles

A circle is the set of all points equidistant from a central point. Its standard equation is $(x - h)^2 + (y - k)^2 = r^2$, where (h, k) is the center and r is the radius.

Problem 5: Finding the Equation of a Circle

Problem: Write the equation of the circle with center $(3, -2)$ and radius 4.

Solution: Using the standard equation $(x - h)^2 + (y - k)^2 = r^2$:

Here, $(h, k) = (3, -2)$ and $r = 4$.

Substituting the values:

$$(x - 3)^2 + (y - (-2))^2 = 4^2$$

$$(x - 3)^2 + (y + 2)^2 = 16$$

This is the standard form of the circle's equation. Expanding it gives the general form: $x^2 - 6x + 9 + y^2 + 4y + 4 = 16$, which simplifies to $x^2 + y^2 - 6x + 4y - 3 = 0$.

3.2 Parabolas

A parabola is the set of all points equidistant from a fixed point (focus) and a fixed line (directrix). Standard forms include $y^2 = 4px$ (opens horizontally) and $x^2 = 4py$ (opens vertically), with variations for vertex at (h, k) .

Problem 6: Identifying the Focus and Directrix of a Parabola

Problem: Find the focus and directrix of the parabola given by the equation $y^2 = 12x$.

Solution: This equation is in the form $y^2 = 4px$. By comparing, we have $4p = 12$, which means $p = 3$.

Since the y term is squared, the parabola opens horizontally. The vertex is at the origin $(0, 0)$.

The focus of a parabola of the form $y^2 = 4px$ is $(p, 0)$. Thus, the focus is $(3, 0)$.

The directrix is the line $x = -p$. Thus, the directrix is $x = -3$.

3.3 Ellipses

An ellipse is the set of all points where the sum of the distances to two fixed points (foci) is constant. The standard equation for an ellipse centered at the origin is $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$ (for a horizontal major axis) or $\frac{x^2}{b^2} + \frac{y^2}{a^2} = 1$ (for a vertical major axis), where $a > b$. a is the semi-major axis and b is the semi-

minor axis.

Problem 7: Finding the Vertices and Foci of an Ellipse

Problem: Determine the vertices and foci of the ellipse $\frac{x^2}{25} + \frac{y^2}{9} = 1$.

Solution: This is an ellipse centered at the origin. Comparing to the standard form $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$, we have $a^2 = 25$ and $b^2 = 9$. Thus, $a = 5$ and $b = 3$. Since a^2 is under the x^2 term, the major axis is horizontal.

The vertices are at $(\pm a, 0)$, so the vertices are $(\pm 5, 0)$.

To find the foci, we first calculate c , where $c^2 = a^2 - b^2$.

$$c^2 = 25 - 9 = 16$$

$$c = 4$$

The foci are located at $(\pm c, 0)$. Therefore, the foci are $(\pm 4, 0)$.

3.4 Hyperbolas

A hyperbola is the set of all points where the absolute difference of the distances to two fixed points (foci) is constant. The standard equation for a hyperbola centered at the origin is $\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$ (opens horizontally) or $\frac{y^2}{a^2} - \frac{x^2}{b^2} = 1$ (opens vertically). For hyperbolas, $c^2 = a^2 + b^2$. The lines $y = \pm \frac{b}{a}x$ are the asymptotes.

Problem 8: Finding the Asymptotes of a Hyperbola

Problem: Find the equations of the asymptotes for the hyperbola $\frac{x^2}{16} - \frac{y^2}{4} = 1$.

Solution: This is a hyperbola centered at the origin with a horizontal transverse axis. Comparing to the standard form $\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$,

$\frac{y^2}{b^2} = 1$, we have $a^2 = 16$ and $b^2 = 4$. Thus, $a = 4$ and $b = 2$.

The equations of the asymptotes for a hyperbola of this form are $y = \pm \frac{b}{a}x$.

Substituting the values of a and b :

$$y = \pm \frac{2}{4}x$$

$$y = \pm \frac{1}{2}x$$

The equations of the asymptotes are $y = \frac{1}{2}x$ and $y = -\frac{1}{2}x$. These lines guide the curve as it extends to infinity.

4. Loci and Geometric Transformations

Analytic geometry is also used to describe loci – sets of points that satisfy certain geometric conditions. Transformations like translations, rotations, and reflections can also be expressed algebraically.

Problem 9: Finding the Locus of a Point

Problem: Find the locus of a point $P(x, y)$ that is equidistant from the points $A(1, 2)$ and $B(5, 6)$.

Solution: The condition is that the distance from P to A is equal to the distance from P to B . Using the distance formula:

$$PA = \sqrt{(x - 1)^2 + (y - 2)^2}$$

$$PB = \sqrt{(x - 5)^2 + (y - 6)^2}$$

Setting $PA = PB$ and squaring both sides to eliminate the square roots:

$$(x - 1)^2 + (y - 2)^2 = (x - 5)^2 + (y - 6)^2$$

Expand both sides:

$$x^2 - 2x + 1 + y^2 - 4y + 4 = x^2 - 10x + 25 + y^2 - 12y + 36$$

Cancel out the x^2 and y^2 terms:

$$-2x + 1 - 4y + 4 = -10x + 25 - 12y + 36$$

Combine constant terms:

$$-2x - 4y + 5 = -10x - 12y + 61$$

Rearrange the terms to form an equation:

$$(-2x + 10x) + (-4y + 12y) = 61 - 5$$

$$8x + 8y = 56$$

Divide by 8:

$$x + y = 7$$

The locus of points equidistant from A and B is the line $x + y = 7$, which is the perpendicular bisector of the segment AB.

5. Three-Dimensional Analytic Geometry

Extending analytic geometry to three dimensions involves using a z-axis. Points are represented by (x, y, z) , and formulas for distance, midpoints, and equations of planes and lines are generalized.

Problem 10: Finding the Equation of a Plane

Problem: Find the equation of the plane passing through the point $(1, 2, 3)$ and having a normal vector $\vec{n} = \langle 2, -1, 4 \rangle$.

Solution: The equation of a plane passing through a point $P_0(x_0, y_0, z_0)$ with a normal vector $\vec{n} = \langle a, b, c \rangle$ is given by $a(x - x_0) + b(y - y_0) + c(z - z_0) = 0$.

Here, $(x_0, y_0, z_0) = (1, 2, 3)$ and $\langle a, b, c \rangle = \langle 2, -1, 4 \rangle$.

$-1, 4 \angle$.

Substituting these values:

$$2(x - 1) + (-1)(y - 2) + 4(z - 3) = 0$$

$$2x - 2 - y + 2 + 4z - 12 = 0$$

$$2x - y + 4z - 12 = 0$$

The equation of the plane is $2x - y + 4z = 12$.

Questions & Answers About analytic geometry problems with solutions

No	Question	Answer
1	What's the quickest way to find the distance between two points on a 2D plane?	Use the distance formula: $d = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2}$. This formula is derived directly from the Pythagorean theorem.
2	How can I find the equation of a line given two points?	First, calculate the slope (m) using $m = \frac{y_2 - y_1}{x_2 - x_1}$. Then, use the point-slope form: $y - y_1 = m(x - x_1)$ and simplify to slope-intercept form ($y = mx + b$).
3	What's the key idea behind finding the midpoint of a line segment?	The midpoint is simply the average of the x-coordinates and the average of the y-coordinates. The formula is $M = (\frac{x_1 + x_2}{2}, \frac{y_1 + y_2}{2})$.
4	How do I determine if two lines are parallel or perpendicular using analytic geometry?	For parallel lines, their slopes are equal ($m_1 = m_2$). For perpendicular lines, the product of their slopes is -1 ($m_1 \cdot m_2 = -1$). This applies to non-vertical and non-horizontal lines.

5	What's the general form of a circle's equation and how do I identify its center and radius?	The general form is $(x - h)^2 + (y - k)^2 = r^2$. The center is (h, k) and the radius is r . To find these from a non-standard equation, you'll often need to complete the square.
6	How do I find the area of a triangle given the coordinates of its vertices?	You can use the determinant formula (also known as the shoelace formula): $\text{Area} = \frac{1}{2} x_1(y_2 - y_3) + x_2(y_3 - y_1) + x_3(y_1 - y_2) $. The absolute value ensures a positive area.
7	What's the difference between the standard and general form of a linear equation, and why is it useful to know both?	The standard form is $Ax + By = C$, while the general form is often $Ax + By + C = 0$. Knowing both is helpful because different problems or contexts might present equations in one form or the other, and conversion is straightforward.
8	How can analytic geometry help us understand conic sections like parabolas, ellipses, and hyperbolas?	Analytic geometry defines these shapes using equations based on distances and loci of points. For example, a parabola is the set of all points equidistant from a point (focus) and a line (directrix), which can be expressed as an equation.
